Introduction
The reported predominant risk factor for infective endocarditis (IE) in studies of children in high resource countries has transitioned from rheumatic heart disease (RHD) to healthcare exposure. This study reports the epidemiology, clinical features, microorganisms and outcomes of IE in a subgroup of children from Queensland, Australia.

Method
Queensland children (0-18 years) with IE presenting to Queensland Children’s Hospital from the opening of the hospital in November 2014 until December 2017 were identified through searches of the Queensland Paediatric Cardiac Service database.

Results
- Twenty children with IE were identified: 11 males and 9 females (Table 1).
- Mean age was 7.9 years (range 8 months to 16 years).
- Three (15%) were of Aboriginal/Torres Strait Islander ethnicity.
- Thirteen (65%) had healthcare-associated IE.
- Three (15%) were of Aboriginal/Torres Strait Islander ethnicity.
- Mean age was 7.9 years (range 8 months to 16 years).
- Twelve (60%) had underlying cardiac pathology.
- Thirteen (65%) had healthcare-associated IE.
- In 19 children (95%) a causative organism was identified (Figure 1).
- Only one case was caused by methicillin resistant Staphylococcus aureus (S.aureus) (MRSA) (12.5% of S. aureus cases) consistent with an MRSA rate of 11.7% in all community associated isolates of S.aureus in Queensland1. There was no fungal IE.
- Median duration of antibiotics was 46 days (range 28-112 days). For the seven patients with methicillin sensitive S.aureus (MSSA), flucloxacillin (6) was the most commonly used antibiotic, with meropenem used for one child who was allergic to penicillin. Adjunctive antibiotics for the children with MSSA-IE included rifampicin, gentamicin and lincomycin.
- Surgery was performed for seven children (35%): vegetation resection and valve repairs (2), right ventricle-pulmonary artery (RV-PA) conduit replacements (2), excision of mitral valve vegetations (3), truncaval valve replacement (1) and removal of an implantable cardioverter defibrillator (ICD) (1).
- There were no deaths from IE. There were significant hospital stays, with mean length of hospitalisation being 49 days (range 20-121 days).

Discussion
These results are consistent with reports from other high resource regions, with respect to epidemiology, risk factors, clinical features and causative organisms. An unexpected finding was the absence of RHD as a risk factor given the relatively high RHD incidence in Australia3.

Indigenous Australians were disproportionately represented; Aboriginal and Torres Strait Islander peoples make up 4% of the Queensland population, yet represented 15% of cases. Only one S.aureus case was methicillin resistant (12.5% of S.aureus cases), consistent with MRSA rate of 11.7% in Queensland S.aureus bacteremia isolates.

There were no deaths among the 20 children studied.

*CHD: Congenital heart disease N = 11. Truncus arteriosus (3), Tetralogy of Fallot (2), Pulmonary atresia with ventricular septal defect (6), Single atrioventricular (right heart) transposition (2), Total anomalous pulmonary venous drainage (1), Ventricular septal defect (6). AHD: Acquired heart disease

Conclusion
IE in this subgroup of Queensland children reflects international trends which include association with CHD and invasive healthcare interventions with S.aureus the most common causative organism. Indigenous children are at increased risk despite lack of association with RHD.
